#### 6.6.1.-

Air is considered to contain 20.9% by volume oxygen and the remainder nitrogen. Calculate the composition of air on mass basis. What is the effective molecular weight of air? Assume air to behave as an ideal gas.

Given:

Volumetric composition of normal air to be oxygen 20.9% and nitrogen 79.1%

Consider one kmol of air, then: mass of oxygen = (Mwt x Vol)<sub>oxygen</sub> = 32 x 0.209

$$= 6.69 \text{ kg/kmol}$$

Similarly, mass of nitrogen = 28 x 0.791 = 22.15 kg/kmol

$$\% \text{ oxygen by mass} = 6.69 \times 100 / (6.69 + 22.15) = 23.20$$

$$\% \text{ nitrogen by mass} = 22.15 \times 100 / (6.69 + 22.15) = 76.80$$

Effective molecular weight of air = mass / molar volume

$$= (6.69 + 22.15 / 1.0 = 28.84 \text{ kg/kmol})$$

6.6.2 –

A natural gas has the following composition by volume: CH<sub>4</sub>: 88.7%, C<sub>2</sub>H<sub>6</sub>: 4.3%, H<sub>2</sub>S: 1.5% and N<sub>2</sub>: 5.5%. Calculate the density of the gas at a temperature of 310K and a pressure of 103.5kPa. What would be the density of the gas if it were diluted by mixing with carbon dioxide so that the combustible components represent 85% by volume of the resulting mixture? Assume ideal gas behaviour,

The composition of the gas by volume is:

CH<sub>4</sub> : 88.7%, C<sub>2</sub>H<sub>6</sub> : 4.3%, H<sub>2</sub>S : 1.5% and N<sub>2</sub> : 5.5%

The combustible components are: CH<sub>4</sub>, C<sub>2</sub>H<sub>6</sub>, and H<sub>2</sub>S .

Assume ideal gas applies to all components of the gas.

$$P/V = m.R.T/ M, \quad \text{i.e. Density, } \rho = P.M / R.T$$

Find the effective molecular weight of the gas, M<sub>g</sub>:

$$M_g = 0.887 \times 16 + 0.043 \times 30 + 0.015 \times 34 + 0.55 \times 28 = 17.532 \text{ kg/kmol}$$

$$\rho_1 = 103.5 \times 17.532 / 8.316 \times 310 = 0.7039 \text{ kg/m}^3$$

Per 100 moles of the original gas the addition of CO<sub>2</sub> will make the fraction of the total combustible components equal to :

$$(n_{\text{CO}_2} + n_{\text{C}_2\text{H}_6} + n_{\text{H}_2\text{S}}) / (100 + n_{\text{CO}_2}) = 0.85$$

$$\text{i.e. } (0.887 + 0.043 + 0.015) / (1.00 + n_{\text{CO}_2}) = 0.945 / (1.00 + n_{\text{CO}_2})$$

When the value of this fraction equals 0.85 then:

$$n_{\text{CO}_2} = (0.945 - 0.85) / 0.85 = 0.118$$

The molecular weight of the new gas =  $\sum n_i M_i / \sum n_i$

$$= (0.887 \times 16 + 0.43 \times 30 + 0.15 \times 34 + 0.055 \times 28 + 0.1118 \times 44) / 1.1118$$

$$= 20.194 \text{ kg/kmol}$$

$$\rho_2 = \rho_1 \times M_{\text{gas2}} / M_{\text{gas1}}$$

$$\rho_2 = 0.7039 \times 20.194 / 17.532 = 0.8107 \text{ kg/m}^3$$

### 6.6.3. –

A high pressure tank of  $0.75 \text{ m}^3$  capacity contains pure hydrogen. What is the mass of the gas if at a temperature of  $287\text{K}$  the pressure is found to be  $1.45\text{MPa}$ ?

After discharging some gas, the pressure became  $0.7 \text{ MPa}$  and the temperature  $279\text{K}$ . How much hydrogen gas was discharged?

For an ideal gas mass is given as:

$$m = P.V / R.T \quad \text{For hydrogen } R = 8.315 / 2.0 \text{ kJ/kg.K}$$

$$m = 1.45 \times 1000 \times 0.75 \times 2 / 8.314 \times 287 = 0.9115 \text{ kg}$$

$$\text{After the gas discharge the mass becomes: } = 0.78 \times 1000 \times 0.75 \times 2 / 8.314 \times 279$$

$$= 0.5043\text{kg}$$

$$\text{Mass of gas discharged} = 0.9115 - 0.5043 = 0.4072\text{kg}$$

### 6.6.4 -

An ideal gas mixture has a molecular weight of  $40 \text{ kg/kmol}$  and a specific heat at constant pressure of  $0.523\text{kJ/kg.K}$ . At a gauge pressure of  $380\text{kPa}$  and  $422\text{K}$  the volume was measured to be  $14.5\text{m}^3$ . Determine: a) the gas constant, b) the specific heat at constant volume and the mass of the gas.

An ideal gas with molecular weight of  $40\text{kg/kmol}$  has a  $C_p$  of  $0.523\text{kJ/kg.K}$

Its volume at a gauge pressure of  $380\text{kPa}$  and  $422 \text{ K}$  is  $14.5\text{m}^3$

$$\text{a) The gas Constant} = 8.3146 / \text{M.Wt} = 8.3146 / 40 = 0.2078 \text{ kJ/kg.K}$$

$$\text{b) For an ideal gas : } C_p - C_v = R$$
